Problem: Given ~~di~~ n and m,

n = no of strings in dictionary

m = no of queries

Only three characters in string - a, b, c

Find whether query[i] is present in dictionary & differ exactly one position.

Approach:
- → store all dictionary string in unordered set.
- → For each query,
  - For each index,
    - temporarily change character
    - check if new string exists
    - Restore character.

Code :- ~~func (n, m, dict~~,

- Input n, m
- Create unordered hash set

for (i = 1 → n)

insert in set

for (each of m Queries)

found = false

for (i = 0 to length (query string) - 1) {

original char = queries[i];

for each char ~~c in~~ (a, b, c)

if c == original char

continue.

query [s[i]] = c;

if query string exists in set : found = true

break

abc

$s[0] \times 26^2 +$

$s[1] \times 26^1 +$

$s[2] \times 26^0$

~~query~~

if found cout << "Yes"

else cout << "No"

TC : $O(S + T)$ S = Total length of dictionary string

T = Total length of Query strings

SC : $O(S)$ set for storing dict

Test case 1: 2 3
